NOVEL NITROPHENYL MUSTARD AND NITROPHENYLAZIRIDINE ALCOHOLS AND THEIR CORRESPONDING PHOSPHATES AND THEIR 10 USE AS TARGETED CYTOTOXIC AGENTS

The present invention relates to novel nitrophenyl mustard and nitrophenylaziridine
alcohols, to their corresponding phosphates, to their use as targeted cytotoxic agents;
as bio-reductive drugs in hypoxic tumours, and to their use in cell ablation, including
15 gene-directed enzyme-prodrug therapy (GDEPT) and antibody-directed enzyme-
prodrug therapy (ADEPT), in conjunction with nitroreductase enzymes.

Background to the invention

20 The use of tumour-selective prodrugs (relatively inactive compounds that can be selectively
converted to more active compounds *in vivo*) is a valuable concept in cancer therapy (see,
for example Denny, *Eur. J. Med. Chem.* (2001) 36, 577).

For example a prodrug may be converted into an anti-tumour agent under the influence of
25 an enzyme that is linkable to a monoclonal antibody that will bind to a tumour associated
antigen. The combination of such a prodrug with such an enzyme monoclonal/antibody
conjugate represents a very powerful clinical agent. This approach to cancer therapy,
often referred to as "antibody directed enzyme/prodrug therapy" (ADEPT), is disclosed in
W088/07378.

A further therapeutic approach termed "virus-directed enzyme prodrug therapy" (VDEPT) has been proposed as a method for treating tumour cells in patients using prodrugs.

Tumour cells are targeted with a viral vector carrying a gene encoding an enzyme capable of activating a prodrug. The gene may be transcriptionally regulated by tissue specific promoter or enhancer sequences. The viral vector enters tumour cells and expresses the enzyme, in order that a prodrug is converted to an active drug within the tumour cells (Huber et al., *Proc. Natl. Acad. Sci. USA* (1991) 88, 8039). Alternatively, non-viral methods for the delivery of genes have been used. Such methods include calcium phosphate co-precipitation, microinjection, liposomes, direct DNA uptake, and receptor-mediated DNA transfer. These are reviewed in Morgan & French, *Annu. Rev. Biochem.*, 1993, 62; 191. The term "GDEPT" (gene-directed enzyme prodrug therapy) is used to include both viral and non-viral delivery systems (Denny et al US 6,310,237).

4-Nitroaromatic compounds are reduced by both mammalian and bacterial flavoprotein enzymes, which effect stepwise addition of up to six electrons. The major enzymatic metabolite is usually the 4-electron reduced species (hydroxylamine).

A number of nitrophenyl mustards and nitrophenylaziridines have been reported as prodrugs for use in gene-directed enzyme-prodrug therapy (GDEPT) in conjunction with nitroreductase enzymes. In particular, CB 1954 [5-(aziridin-1-yl)-2,4-dinitrobenzamide; (1) [shown below] is reported to be a substrate for the aerobic nitroreductase NTR (nfsB gene product) isolated from *E. coli* B (Boland et al., *Biochem. Pharmacol.* 1991, 41, 867-875; Anlezark et al., *Biochem. Pharmacol.* 1992, 44, 2289-2295; Parkinson et al., *J. Med. Chem.* 2000, 43, 3624). This compound has been used as a prodrug in both ADEPT (Knox et al., *Biochem. Pharmacol.*, 1995, 49, 1641-1647) and GDEPT (Bridgewater et al., *Eur. J. Cancer*, 1995, 31A, 2362-2370; Bailey et al., *Gene Ther.*, 1996, 3, 1143-1150; Bailey and Hart, *Gene Ther.*, 1997, 4, 80-81; Green et al., *Cancer Gene Ther.*, 1997, 4, 229-238) applications, including a clinical trial (Chung-Faye et al., *Clin. Cancer Res.*, 2001, 7, 2662-2668).

Similarly, the dinitrophenyl mustard SN 23862 (**2**) is also a substrate for NTR, and shows selective toxicity towards cell lines that express the enzyme. It is activated by nitro group reduction (Palmer et al., *J. Med. Chem.*, 1995, 38, 1229; Kestell et al., *Cancer Chemother. Pharmacol.*, 2000, 46, 365-374). The 4-SO₂Me derivative (**3**) was also a substrate (Atwell et al., *Anti-Cancer Drug Des.*, 1996, 11, 553), as were the regioisomers (**4**) and (**5**) (Friedlos et al., *J. Med. Chem.*, 1997, 40, 1270).

10

However, compounds of this type were not very effective as bioreductive prodrugs when these compounds were activated in hypoxic tumour tissue by endogenous reductase enzymes, showing potency ratios of 2-5 fold under hypoxic conditions relative to oxic conditions in the wild-type AA8 cell line, using a clonogenic assay (Palmer et al., *J. Med. Chem.* 1996, 39, 2518-2528).

Some phosphate analogues of mustards have been described, for the purpose of solubilising the compounds. The best known is estramustine phosphate (Estracyt; **6**), which has been shown to bind to tubulin binding domains on various microtubule-associated proteins (Moraga et al., *Biochim. Biophys. Acta*, 1992, 1121, 97-103), and which has been shown to be active in advanced breast cancer (Keren-Rosenberg et al., *Semin. Oncol.*, 1997, 24 (Suppl. 3), 26-29), but has not been shown to be activated by NTR or hypoxia. Another study has also shown estramustine phosphate to be a radiation sensitizer (Kim et al., *Int. J. Radiat. Oncol. Biol. Phys.*, 1994, 29, 555-557). The phenol mustard phosphate analogue **7** is a carboxypeptidase substrate that is not activated under hypoxic conditions, (Matsui et al., Japanese Patent 07082280 A2, 1995), and the solubilised mustard **8** has been

described as a phosphatase inhibitor but has not been shown to be activated under hypoxic conditions (Workman, Chem.-Biol. Interact., 1978, 20, 103-112).

5

It is an object of the present invention to provide a specific class of nitrophenyl mustards and aziridines, bearing short-chain alcohols, and their corresponding phosphates for use as targeted cytotoxic agents or bioreductive prodrugs or to at least provide the public with a useful alternative.

As used throughout the specification the pharmaceutically acceptable derivatives and salts thereof include acid derived salts formed from are hydrochloric, sulfuric, phosphoric, acetic, citric, oxalic, malonic, salicylic, malic, fumaric, succinic, ascorbic, maleic, methanesulfonic, isethionic acids and the like and base derived salts formed from sodium and potassium carbonate, sodium and potassium hydroxide, ammonia, triethylamine, triethanolamine and the like.

As used throughout the specification, the term cell ablation is to be understood as the killing of cells, that have been engineered to express an enzyme, such as a nitroreductase, by administration of a prodrug that is activated by that enzyme. As a result, cell ablation can be used to selectively ablate specified target cells or tissue through specific enzymatic expression of a nitroreductase for example, that is specifically expressed by the tissue and which can then be employed to activate a prodrug into an active metabolite to ablate the specified target cells or tissue. (Gusterson *et al. Endocrine Related Cancer*, 1997, 4, 67-74.)

The expression “substantially minimal bystander effect” is to be understood as meaning that the killing of adjoining non-targeted cells is minimal because there is little or no diffusion between the targeted and non-targeted cells of an activated metabolite that arises from the enzymatic activation of a compound of Formula (I) or Formula (II) as defined above or a compound of any one of compounds Ia-Ic, or IIa-IIc as defined above or a mixture thereof.

Pharmaceutically acceptable salts of formula (I) include the basic or acidic compounds of formula (I) that form pharmaceutically acceptable salts with both organic and inorganic acids and/or organic and inorganic bases. Examples of suitable acids for salt formation are hydrochloric, sulfuric, phosphoric, acetic, citric, oxalic, malonic, salicylic, malic, fumaric, succinic, ascorbic, maleic, methanesulfonic, isethionic, and the like. Examples of suitable bases for salt formation are sodium and potassium carbonate, sodium and potassium hydroxide, ammonia, triethylamine, triethanolamine, and the like.

Further aspects of the present invention will become apparent from the following description given by way of example only and with reference to the accompanying synthetic schemes.

- 5 Examples of the compounds of Formula (I) where X is $-\text{CONH}-$ can be prepared by the processes described in Scheme 1, where Z is as defined above for Formula (I).

10 Examples 1-25 (alcohols) and Examples 26-39 (phosphates).

Example 1 (Scheme 2a). N-(3-Hydroxypropyl)-5-[bis(2-chloroethyl)amino]-2,4-dinitrobenzamide (IIa-3). A suspension of 5-[bis(2-chloroethyl)amino]-2,4-dinitrobenzoic acid [Palmer et al., J. Med. Chem., 1994, 37, 2175] (**1**) (2.50 g, 7.1 mmol) in SOCl_2 (20 mL) containing DMF (2 drops) was heated under reflux for 1 h, then concentrated to dryness under reduced pressure and re-evaporated with benzene. The resulting crude benzoyl chloride was dissolved in Me_2CO (50 mL) and the cooled (-5°C) solution was treated with a cold solution of 3-amino-1-propanol (1.09 g, 14.5 mmol) in water (25 mL). The reaction mixture was shaken at room temperature for 5 min, then diluted with water (25 mL), concentrated to half volume, and extracted with CH_2Cl_2 (2x). The organic extract was washed with 0.1 N HCl and water then worked up to give a solid which was chromatographed on silica gel, eluting with EtOAc to give **IIa-3** (2.37 g, 82%); mp (EtOAc/ $i\text{-Pr}_2\text{O}$) $90\text{--}91^\circ\text{C}$; ^1H NMR [$(\text{CD}_3)_2\text{SO}$] δ 8.63 (t, $J = 5.6$ Hz, 1 H, CONH), 8.53 (s, 1 H, H-3), 7.42 (s, 1 H, H-6), 4.46 (t, $J = 5.1$ Hz, 1 H, OH), 3.82 (t, $J = 5.9$ Hz, 4 H, $\text{N}(\text{CH}_2\text{CH}_2\text{Cl})_2$), 3.68 (t, $J = 5.9$ Hz, 4 H, $\text{N}(\text{CH}_2\text{CH}_2\text{Cl})_2$), **3.49** (q, $J = 6.0$

Representative alcohols of Formula (I) (listed in Table 1a) show selective cytotoxicity towards human cancer cell lines transfected with either the *E. coli* nitroreductase cDNA (NTR) (Table 3, columns 2 and 3), or human cytochrome P450 reductase (P450R) under
5 hypoxic conditions (Table 3, columns 4 and 5). In this table, sensitivity ratios are displayed to indicate the degree of selectivity for either NTR expression (column 3) or hypoxia (column 5). However, overexpression of P450R is not required for hypoxic selectivity.

IC₅₀ values are derived from cell proliferation experiments, following 4 hour drug exposure under a gas phase of either 20% oxygen or 0% oxygen (anoxia, achieved using an anaerobic chamber). Cells were grown under aerobic conditions for a further 5 days, and cell density estimated using the sulphorhodamine B assay, to determine the
5 concentration of prodrug required to inhibit growth to 50% of control.

The activity of the phosphates as hypoxic cytotoxins is demonstrated by the data in Figure 1 for the representative example (**Ib-7P**). This employs an *in vivo* excision assay with the Rif-1 tumour, where the oxic tumour cells are sterilised using 15Gy of radiation, and the

cytotoxicity of an agent against the remaining hypoxic cells can be quantitated.

Unexpectedly, the activity of the phosphate **Ib-7P** is found to exceed that of its parent alcohol (**IIb-7**) at their respective maximum tolerated doses (**Ib-7P** = 750 $\mu\text{mol/kg}$; **IIb-7** = 1000 $\mu\text{mol/kg}$). This experiment demonstrates that the phosphate **Ib-7P** is more active
5 against hypoxic cells than the reference hypoxic cytotoxin tirapazamine, and that it is more active against hypoxic cells than oxic cells (i.e. when given post irradiation than when given without irradiation). Thus **Ib-7P** acts as a hypoxia-selective cytotoxin *in vivo*. Although less active against oxic tumour cells, this activity is significant demonstrating that the compound also has utility as a single agent (without radiation).

The notable activity of the phosphates of Formula (I) against hypoxic cells in human tumour xenografts is illustrated by the data of Table 4. In these experiments SiHa human cervical carcinoma cells were grown subcutaneously in CD-1 nude (immunodeficient) mice. The compounds were administered at doses corresponding to 75% or 20% of the maximum tolerated dose (MTD), 5 minutes after a whole body dose of ionising radiation (cobalt-60 gamma radiation) sufficient to sterilise the oxic cells (15 Gy). The tumours were excised 18 hours later, dissociated with a cocktail of proteases, and cell survival was determined using a clonogenic assay. The logarithms of cell kill were calculated from the difference in the numbers of clonogens per gram tumour tissue between treated and control tumours. All of the phosphates tested showed large effects against hypoxic cells at 75% of the MTD (Table 4, column 4). This was selective for hypoxia as demonstrated by the lesser cell kill in the absence of radiation. However, cell killing by the compounds alone was significant in all cases (Table 4, column 5) demonstrating that the compounds also have antitumour activity as single agents. Activity against hypoxic cells was also demonstrated for the same compounds at doses corresponding to only 20% of the MTD (Table 4, column 7). The reference hypoxic cytotoxin tirapazamine, and the reference nitrogen mustards (melphalan, chlorambucil and cyclophosphamide) lacked activity at 20% of their respective MTDs.

A representative example of the phosphates of Formula (I) as NTR activated cytotoxins is provided in Figure 2. In the WiDr *in vivo* growth delay assay, xenografts containing mixtures of WiDr^{WT} and WiDr^{NTR} cells are grown to 300mm³ and treated with a single dose of prodrug at its MTD. Tumour growth is monitored over time and animals are euthanased when mean tumour volume >1600mm³. Data is presented as time to death. Unexpectedly, the activity of the phosphate (Ib-7P) is observed to exceed that of its parent alcohol (Ib-7), when administered at their respective maximum tolerated doses (750 µmol/kg). Ib-7P is superior to Ib-7 with respect to (i) time to first treatment failure (77- days vs. 17-days) and (ii) over-all survival (40% vs. 6%).

Pharmacokinetics of the phosphate esters Ib-2mP, Ib-7P, Ib-12P and Ic-12P following administration to female CD-1 nude mice by intraperitoneal injection at a dose corresponding to 75% of the maximum tolerated dose. Monosodium salts of the compounds were dissolved in phosphate buffered saline, pH 7.4, with addition of one equivalent of sodium bicarbonate. Serial blood samples were obtained by small tail vein bleeds, and 10 μ l of plasma was prepared from each. Proteins were precipitated by addition of 3 volumes of methanol, and concentrations of the phosphate esters and corresponding alcohols were determined by HPLC using either UV or mass spectrometry detection.
